

Measures of Spread

Range, Variance and Standard Deviation

- Example Datasets:

$$\mathbf{X} = (10, 0, 10, 20, 30) \quad \text{and} \quad \mathbf{Y} = (8, 9, 10, 11, 12)$$

- Population Mean:

$$\mathbf{X} = \mu = \frac{(10 + 0 + 10 + 20 + 30)}{5} = \boxed{10}$$

$$\mathbf{Y} = \mu = \frac{(8 + 9 + 10 + 11 + 12)}{5} = \boxed{10}$$

- Population Range: The difference between the high & low datapoints in dataset.

$$\mathbf{X} = (30 - (-10)) = \boxed{40} \quad \text{and} \quad \mathbf{Y} = (12 - 8) = \boxed{4}$$

- Variance: Sum of squared differences of datapoints divided by total.

$$\mathbf{X} = \sigma^2 = \frac{(-10 - 10)^2 + (0 - 10)^2 + (10 - 10)^2 + (20 - 10)^2 + (30 - 10)^2}{5}$$

$$= \frac{1000}{5} = \boxed{200^{u^2}}$$

$$\mathbf{Y} = \sigma^2 = \frac{(8 - 10)^2 + (9 - 10)^2 + (10 - 10)^2 + (11 - 10)^2 + (12 - 10)^2}{5}$$

$$= \frac{10}{5} = \boxed{2^{u^2}}$$

Summary: We can clearly see which dataset has the greater variance or spread. But the result σ^2 is a unit squared, meters, miles, etc. which brings us to finding the standard deviation σ .

- Standard Deviation:

$$\mathbf{SD} = \sqrt{\text{variance}} = \sqrt{\sigma^2} = \sigma \quad \text{then,} \quad \sigma = \sqrt{200} = 10\sqrt{2} \quad \text{and} \quad \sigma = \sqrt{2}$$

Sample Variance

Sample Variance and Standard Deviation

- Sample Datasets:

$$\mathbf{X} = (10, 20, 30) \quad \text{and} \quad \mathbf{Y} = (10, 11, 12)$$

- Sample Formula:

$$\frac{\sum_{i=1}^n (x_i - \bar{x})^2}{n - 1}$$

Explanation Sum of all datapoints from $i = 1$, denoted with lowercase n , which is convention for the sample (uppercase N denoting the population), then taking each datapoint x_i , and from it subtracting the sample mean \bar{x} , then dividing it by one less than the total datapoints $n - 1$.

- **Sample Mean:**

$$X = \bar{x} = \frac{(10 + 20 + 30)}{2} = \boxed{30}$$

$$Y = \bar{y} = \frac{(10 + 11 + 12)}{2} = \boxed{16.5}$$

- **Sample Range:** The difference between the high & low datapoints in dataset.

$$X = (30 - 10) = \boxed{20} \quad \text{and} \quad Y = (12 - 10) = \boxed{2}$$

- **Unbiased Sample Variance:** Sum of squared differences of datapoints divided by total minus one.

$$S_{n-1}^2 = \frac{(10 - 30)^2 + (20 - 30)^2 + (30 - 30)^2}{2}$$

$$= \frac{500}{2} = 250^{u^2}$$

$$S_{n-1}^2 = \frac{(10 - 16.5)^2 + (11 - 16.5)^2 + (12 - 16.5)^2}{2}$$

$$\approx \frac{92.75}{2} \approx 46.38^{u^2}$$

Summary: We can clearly see which dataset has the greater variance or spread. But the result σ^2 is a unit squared, meters, miles, etc. which brings us to finding the standard deviation σ .

- **Sample Standard Deviation:**

$$SSD = \sqrt{variance} = \sqrt{S_{n-1}^2} = S$$

then,

$$S = \sqrt{250} = 5\sqrt{10} \approx 15.81 \quad \text{and} \quad S \approx \sqrt{46.38} \approx 6.81$$

Note Because the square root function is non-linear, this actually is not a true unbiased estimate of the population standard deviation. We use this sample variance to calculate the sample standard deviation but it is NOT unbiased.
